④ Scriptlet tag : begins with `<%` and ends with `%>`. We can embed any amount of java code in the JSP scriptlets. JSP engine places these code in `-jspService()` method.

```
<% int i=6; i=i+9; %>
```

⑤ Action Tags : Three main roles.

- enable the use of server side Javabeans
- transfer control between pages.
- browser independent support for applets.

```
<jsp:usebean id="test" scope="application" class="com.tech.test"/>
```

Ques2

(a) Insert a record in Product table using JDBC and JSP.

```
<% page import="java.sql.*" %>
<HTML>
  <HEAD>
    <TITLE> Insertion in Product Table </TITLE>
  </HEAD>
  <BODY>
    <H1> Inserting Data </H1>
    <%
      Connection con = null;
      Class.forName("sun.jdbc.odbc.JdbcOdbcDriver");
      Connection con = DriverManager.getConnection("jdbc:odbc:Access");
      Statement stmt = null;
      stmt = con.createStatement();
      String sql = "INSERT INTO Product(id, name, quantity, Price)
        VALUES (2, 'Shampoo', 36, 150);";
      stmt.executeUpdate(sql); %>
    </BODY>
  </HTML>
```

(b)
Solution 2 Types of JDBC drivers

Type 1: JDBC-ODBC Bridge
 They are JDBC-ODBC Bridge drivers. They delegate the work of data access to ODBC API. ODBC is widely used by developers to connect to a databases in a non-Java environment. This kind of driver is generally most appropriate when automatic installation of a java technology is not important.
 Advantage:- It acts as good approach for learning JDBC. It may be useful for compomes that already have ODBC drivers installed on each client machine - typically the case for windows based m/c running productivity applications.
 Disadvantages - It is not suitable for large-scale applications. They are the slowest of all. The performance of system may suffer because there is some overhead associated with the translation work to go from JDBC to ODBC. It doesn't support all features of java.

Type 2 - Native-API partly java technology-enable driver.
 They mainly use native API for data access and provide Java wrapper classes to be able to invoked using JDBC drivers. It converts the calls to that a developer writes to the JDBC application programming interface into calls that connect to the client machine's application programing interface for a specific database such as IBM, etc. this style of driver requires that some binary code be loaded on each client machine. (5)

www.vijay-jotani.weebly.com

WWW.VIJAY-JOTANI.WEEBLY.COM

Advantage:- It has a better performance than that of Type1, in part because the Type2 driver contains compiled code that's optimised for the back-end database server's operating system.

Disadvantage: For this, User needs to make sure the JDBC driver of the database vendor is loaded onto each client machine. Must have compiled code for every operating system that the application will run on. Best use is for controlled environments such as internet.

Ques 3 (a) Telephone enquiry system

```
import javax.ejb.*;
import java.rmi.RemoteException;
public interface Telephone extends EJBObject {
    public String getTelephoneNumber() throws RemoteException;
    public void setTelephoneNumber(String String TelephoneNumber)
        throws RemoteException;
    public String getName() throws RemoteException;
    public void setName (String name) throws RemoteException;
    public Integer getOfficialExtension() throws RemoteException;
    public void setOfficialExtension(Integer Integer officialExtension)
        throws RemoteException;
    public Integer getExtension() throws RemoteException;
    public void setExtension (Integer extension) throws
        RemoteException;
}
```

(b)
Solution

A session bean is an EJB that is created by a client and usually exists only for the duration of a single client-server session. A session bean usually performs operations such as calculations or database access on behalf of the client. While a session bean may be transactional, it is not recoverable if a system crash occurs. Session bean objects can be stateless or they can maintain a conversational state across methods and transactions.

WWW.VIJAY-JOTANI.WEEBLY.COM

n) If a session bean maintains a state, the ESB container manages this state if the object must be removed from memory. However, persistent data must be maintained by the session bean object itself.

The tools for a container generate additional classes for a session bean at deployment time. These tools obtain information from the ESB architecture by examining its classes and interfaces. This information is utilised to generate two classes dynamically that implement the home and remote interfaces of the bean. These container generates a Serializable Handle class as well which provides a way to identify a session bean instance within a specific lifecycle. These classes can be implemented to perform customized operatized operations and functionally when mixed in with contain-specific code.

An entity bean is an object representation of persistent data maintained in a permanent data store such as a database. A primary key identifies each instance of an entity bean. Entity beans are transactional and recoverable in the event of a system crash.

Entity Bean are representation of explicit data or collection of data, such as a row in a relational database. Entity bean methods provide procedures for acting on the data representation of the bean. A entity bean is persistent and survives as long as it data remains in the database.

(b)
Solution: XML Entity
 Entity declarations allow you to associate a name with some other fragment of the document. That construct can be a chunk of regular text, a chunk of the document type declaration or a reference to an external file containing either text or binary data. There are three varieties of entities in XML.
 Internal entity - Internal entities allow you to define shortcuts for frequently typed text or text that is expected to change, such as the revision of a document.
 External Entity - allow an XML document to refer an external file.
 Parameter Entities - can only occur in the document type declaration. It is identified by placing % in front of its name in the declaration.
 XML is better than HTML because it offers Data Semantics, XML allows you to make the semantics of your data unambiguous. It allows you to call a spade a <spade>. On the other hand HTML describes presentation and XML describes content. XML is aimed towards being both human and machine readable. XML does not contain any information indicating how the document should be rendered in a browser. Therefore, XML factors data from presentation. The beauty of this feature is that the same data can be presented in a variety of ways without having to replicate any data.

Ques

(a) Entity Beans actually represent the data in a database. It is not that Entity Beans replace JDBC API. There are two types of Entity Beans container Managed and Bean managed.

In container managed entity bean - whenever the instance of the bean is created the container automatically retrieve the data from DB/Persistence storage and assigns to the object variables in bean for user to manipulate or use them. For this the developer needs to map the fields in the database to the variables in deployment descriptor files.

In Bean Managed Entity bean - The developer has to specifically make connection, retrieve values, assign them to the objects in the ejbload() which will be called by the container when it instantiates bean object. Similarly in the ejbStore() the container saves the object values back the persistence storage. ejbload and ejbStore are callback methods and can be only invoked by the container.

Apart from this, when you use Entity beans you don't need to worry about database transaction handling, database connection pooling etc. which are taken care by the ejb container. But in case of JDBC you have to explicitly do the above features.

The great thing about the entity beans of container managed, whenever the connection is failed during the transaction processing, the database consistency is maintained automatically. The container writes the data stored at persistent storage of the entity beans to the database again to provide the writes the data stored at data stored at persistent storage of the entity beans to the database again to provide database consistency. (as where as in jdbc api, we,

(b)
Solution: Validating and non validating parser
 XML parser, which enforces the DTD rules on the XML document, is known as the validating parser, whereas the XML document which ignores DTD rules, is known as the non-validating parser. The non-validating parser checks that you know what you are doing, but non-validating parser checks only when it is well-formed, that you have matching start and end tags. The validating parser validates your XML against your schemas. To check that you have got the proper datatypes, filled in all mandatory attributes etc. A non validating parser checks if a document follows the XML syntax rules. It builds a tree structure from the tags used in XML document and return an error only when there is a problem with the syntax of the document. Non validating parsers process a document faster because they do not have to check every element against a DTD. In other words, these parsers check whether an XML document adheres to the rules of well formed document. The Expat parser is an example of non validating parser. A validating parser check the syntax, builds the tree structure, and compares the structure of the XML document with the structure specified in the DTD associated with the document. In other words, in addition to checking whether an XML document is well formed, validating parser also check whether the XML document adheres to the rules in the DTD associated with the XML document. eg Microsoft MSXML parser.

Ques 6
 (a) SSL Authentication in java clients

(i) JSSE (Java Secure Socket Extension) and Web Logic
 JSSE is a set of packages that support and implement the SSL and TLS v1 protocols, making those capabilities available. BEA Weblogic Server provides Secure Sockets Layer (SSL) support for encrypting data transmitted b/w Weblogic Server clients and servers, Java clients, web browsers and other servers. Web Logic Server's Java Secure Socket Extension (JSSE) implementation can be used by Weblogic clients. Other JSSE implementations can be used for their client-side code outside the server as well.

(ii) Using JNDI Authentication
 Java clients use the JNDI to pass on credentials to the Weblogic Server. A Java client establishes a connection with Weblogic Server by getting a JNDI initial-context. The Java client then, uses the InitialContext to look up the resources it needs in the Weblogic Server JNDI tree.

(iii) SSL certificate Authentication Development Environment.

- SSL Authentication API's.
 To implement Java clients that use SSL authentication on Weblogic Server, you use a combination of Java SDK application programming interfaces (API) and Weblogic API.
- SSL Client Application components
 SSL clients comprises following components at minimum.
 - Java Client
 - Hostname Verifier
 - HandshakeCompletedListener
 - TrustManager

Hi everyone, I am **Akanksha**. I am not sure if all the answers are correct or not but this i come up with. Please read carefully before writing, I am not responsible for anything th all.

Example: SSLSocketClient sample code

The SSLSocketClient sample demonstrates how to use SSL sockets to go directly to the secure port to connect to a ISP served by an instance of WebLogic Server and display the results of that connection. It shows how to implement the following functions -

- Initializing an SSLContext with client identity, a HostnameVerifier JSSE and a TrustManager JSSE
- Creating a keystore and retrieving the private key and certificate chain
- Using an SSLSocketFactory
- Using HTTPS to connect to a ISP served by WebLogic server.
- Implementing the javax.net.ssl.HandshakeCompletedListener interface
- Creating a dummy implementation of the weblogic.security.SSL.HostnameVerifier JSSE class to verify that the server the example connects to is running on the desired host.

```

import java.io.File;
import java.io.*;
import java.util.Hashtable;
import java.security.*;
import weblogic.security.SSL.HostnameVerifierJSSE;
import weblogic.security.SSL.SSLContext;
import javax.net.ssl.SSLSocket;
import javax.net.ssl.SSLSession;
import weblogic.security.SSL.SSLSocketFactory;
import weblogic.security.SSL.TrustManagerJSSE;

public class SSLSocketClient {
    public void SSLSocketClient() {}
    public static void main (String [] arg) throws IOException {

Thank to all of you, i m now in malaysia..
 btw i have a question "would u like to be a friendship with me?"
 yaar bahut lonely ho gya hu guyz :))

Hi everyone, I am Akanksha. I am not sure if all the answers are correct or not but this i come up with. Please read carefully before writing, I am not responsible for anything th all.

(b) Digital Certification
 Digital certificates provide a mechanism to authenticate and secure information on open networks. Applications using this mechanism include secure email, secure web applications, digital signing of software files, smart card authentication, and encrypting file systems. Certificates are a key building block for providing security services within an IT infrastructure, usually referred to as a public key infrastructure (PKI). This PKI infrastructure will then enforce user authentication, network encryption, data integrity and non-repudiation of origin for the data.

Constituents of a digital Certification
 The basic components within a digital certificate include:

- the name of the user/entity being certified
- the public key of the user/entity
- the name of the certification authority
- a digital signature.

The certificate provides a binding link between a user/entity and a public key, so the certificates must use a well defined name space for the user/entity being identified. The International Telecommunication Union X.509 specification [3] provides a set of standards for the implementation of a public key infrastructure - one being for the structure of a digital public key certificate.

While many computer users and students of computing or information science are aware that digital certificates play a role in secure data exchange, the full nature and application of the associated technology is difficult to embrace. One source for this difficulty is the range of component technologies that combine in order to afford data security.

In order to clarify the relationship between central technologies such as symmetric and asymmetric encryption, digital signatures, certificate key stores, certificate revocation lists, and the use of digital certificates in secure web transactions, we have developed a software tool that allows users to explore these aspects of data security.

Quest 7

(a) Recovery Procedures

When a trusted system fails, it is very important that the failure does not compromise the security policy requirements. The recovery procedures also should not give any opportunity for violation of the system's security policy. The system restart must be in a secure mode. Startup should be in the maintenance mode that permits access the only privileged users from privileged terminals.

Fault-tolerant System - In this system, the computer or network continues to function even when a component fails. This system has the capability of detecting the fault and correcting the fault as well.

Fail-safe System - here, the program execution is terminated and the system is protected from being compromised when a system failure occurs is detected.

Failsoft or resilient - when a system failure occurs and is detected, selected not critical processing is terminated. The system continues to function in a graded mode.

Failover - This refer to switching to a duplicate "hot" backup component in real time when a hardware or software failure occurs.

Cold Start - This is required when a system failure occurs and the recovery procedures cannot return the system to a known, reliable, secure state.

(b) Type 2 Drivers
 Native-API partly Java technology - enable driver
 They mainly use native API for data access and provide Java wrapper classes to be able to be invoked using JDBC drivers. It converts the calls that a developer writes to the JDBC application programming interface into calls that connect to the client machine's application programming interface for a specific database such as IBM, Oracle etc like, the bridge driver, this style of driver requires that some binary code be loaded on each client machine.

Advantage - It has a better performance than Type1, in part because the Type2 driver contains compiled code that's optimised for back-end database servers's operating systems

Disadvantage - For this, user needs to make sure the JDBC driver of the database vendor is loaded onto each client machine. eg → Oracle Call Interface (OCI) driver

Type 4 Drivers also known as 100% Pure Java.
 A native-protocol fully java technology - enabled driver
 It is direct-to-database pure Java driver. It converts JDBC technology calls into the network protocol used by different DBMS directly. Basically it converts JDBC calls into packet that are sent over the network in the proprietary format used by the specific database. Allows a direct call from the client machine to the database.

Advantage - It again has better performance than Type1 and 2 and there is no need to install special software on client server. It can be downloaded dynamically.

WWW.VIJAY-JOTANI.WEEBLY.COM

WWW.VIJAY-JOTANI.WEEBLY.COM

Disadvantage - It is not optimised for server operating system, so the driver can't take advantage of operating system features. For this, user needs a different driver for each different database eg MySQL's connector.

Type2 and Type4 drivers

Ques 8

(a) Solution: Invoking Servlet

You can invoke a servlet by directly addressing it from a web page with a URL or by calling programmatically from an already running servlet.

- Calling a servlet with a URL

You can call servlets by using URLs embedded as links in HTML or JSP pages. The format of the URL is as follows -

http://server:port/context_root/servlet/servlet_name?name=value

- Calling a servlet Programmatically

First, identify which servlet to call by a specific URI. This URI is normally a path relative to current application. You can call servlet programmatically in two ways

To include another servlet output, use the `include()` method from `ResponseDispatcher` interface.

To handle interaction control to another servlet, use the `RequestDispatcher` interfaces `forward()` method with the servlet's URI as a parameter.

Servlet Life Cycle

Servlet are normal java classes, which are created when needed and destroyed when not needed. A java servlet has a lifecycle that defines how the servlet is loaded and initialized, how it receives and responds to requests, and it is taken out of service. In code, the servlet lifecycle is defined by the `javax.servlet.Servlet` interface. Since Servlets run within a Servlet Container, creation and destruction of Servlets is the duty of Servlet Container. Implementing the `init()` and `destroy()` methods of Servlet interface allows you to be told by the servlet container that when it has created an instance of your servlet and when it has destroyed that instance. An important point to remember is that your servlet is not created and destroyed for every request it receives, rather it is created and kept in memory where requests are forwarded to it and your servlet then generates response.

```

graph TD
    A[Servlet Class] --> B[Instantiating & loading  
Servlet Engine can instantiate  
more than one Servlet instance]
    B --> C[Initialisation (ServletConfig)  
Method]
    C --> D[Ready Service Method  
A Service Method executes  
for each Servlet interface]
    D --> E[Destruction  
Destroy() Method]
    E --> F[Garbage Collection  
The server no longer has a  
reference to the object]
  
```

Hi everyone, I am Akanksha. I am not sure if all the answers are correct or not but this i come up with. Please read carefully before writing, I am not responsible for anything th all.

WWW.VIJAY-JOTANI.WEEBLY.COM

WWW.VIJAY-JOTANI.WEEBLY.COM

Three principal stages

1) Servlet Initialisation - This is the first stage, the servlets constructor is called together with Servlet method `init()` this is called automatically once during the servlet's execution life cycle and can be used to place any one-off initialisation such as opening a connection to a database.

2) Servlet Execution - Once your Servlet is initialised and its `init()` method called, any request that the Servlet Container receives will be forwarded to your Servlet's `service()` method. `HttpServlet` class breaks this `service()` method into more useful `doGet()`, `doPost()`, `doDelete()`, `doOptions()`, `doPut()` & `doTrace()` methods depending on the type of HTTP request it receives. So in order to generate response you should override the `doGet()` or `doPost()` method as per your requirement.

3) Servlet Destruction - When your application is stopped or Servlet Container shut down, your Servlets `destroy()` method will be called to clean up any resources allocated during initialisation and to shutdown gracefully.

(b) Deployment descriptor
Definition A deployment descriptor is a configuration file of web application or EJB application which is to be deployed to web or EJB container. The deployment descriptors should contain a standard structural information for all enterprise beans in an EJB application.
 The deployment descriptor is an xml file that contains the basic and most important information that is required to deploy a web application (Servlet). Without this, web server would not know, which requests to entertain/consider as requests to access this servlet.
